[기본] 1 주어진 글 다음에 이어질 글의 순서로 가장 적절한 것을 고르시오.

> Every map is, in a precise sense, a lie of omission. A cartographer who tried to record every pebble, fence post, and blade of grass would end up with a map as large as the territory itself — and therefore perfectly useless.

(A) Consider two maps of the same city drawn for two such users. A transit map freely distorts distances so that connections become legible at a glance, while a tourist map inflates landmarks and shrinks residential blocks to near invisibility. Laid side by side, the two are barely recognizable as the same place.

(B) The cartographer’s craft, then, lies less in what is included than in what is deliberately left out. Every omission encodes a judgment about what the map’s eventual user will need — and different users need strikingly different things.

(C) Neither, however, is mistaken. Each is faithful to a purpose rather than to the ground, and to judge a map by its completeness rather than by its fitness for that purpose is to misunderstand what maps are for.

> When a government announced that hospitals would be penalized if emergency patients waited more than four hours to be seen, the policy seemed beyond criticism. Shorter waits are plainly better than longer ones, and a clear target promised accountability.

(A) Some patients, for instance, were wheeled onto trolleys in corridors and formally “admitted” minutes before the deadline, though nothing about their treatment had changed. On paper, waiting times fell dramatically.

(B) What the episode illustrates is a pattern far older than modern medicine: once a number becomes the goal, it ceases to be a trustworthy window onto the reality it was designed to reveal.

(C) Within a year, the figures did improve — but not always in the way policymakers had imagined. Under pressure to hit the target, hospitals discovered that it was often easier to change what was being counted than to change what was actually happening.

> Children acquiring English pass through a curious phase. Having used irregular past-tense forms such as “went” and “broke” correctly for months, many abruptly begin to say “goed” and “breaked.”

(A) That rule, however, is initially applied too broadly, sweeping up verbs that should have been left alone. Only with further exposure do children learn to fence off the exceptions, and the correct forms reappear — this time as part of a system rather than as memorized fragments.

(B) To parents, this looks like regression. In fact, it signals a leap forward. The early correct forms were most likely stored as unanalyzed wholes, copied directly from adult speech without any grasp of their internal structure.

(C) The errors, by contrast, reveal that the child has extracted a general rule from the many regular verbs she hears — add “-ed” to mark the past — and is now producing forms no one around her has ever uttered.

> A lecturer finishes a dense explanation and asks, “Any questions?” The room stays silent. Taking the silence as a sign that the material has landed, she moves on to the next topic.

(A) Often, however, a large share of the room is lost. Most students are privately confused, but they glance around, see no raised hands, and interpret the stillness of their peers in a particular way.

(B) The trap, then, is that a group can sustain a belief that almost none of its members privately holds. Breaking it usually takes just one person willing to act on private doubt rather than on public appearance — and that single raised hand frequently releases a flood of others.

(C) Specifically, each student reads the silence as proof that everyone else has understood. Unwilling to be the only one confused, each stays quiet — and in doing so, adds to the very silence that misled the others.

> When the researchers then cut both prices by one cent, making the ordinary chocolate free, the majority abruptly reversed their choice.

Economists have long assumed that people respond to prices smoothly: lower a price by a small amount, and demand rises by a correspondingly small amount. (①) Experiments on what is now called the “zero-price effect” suggest that this assumption breaks down at one particular point. (②) In one study, shoppers were offered a choice between a premium chocolate for 15 cents and an ordinary one for 1 cent; most chose the premium chocolate, a sensible decision given the gap in quality. (③) Yet the relative difference was unchanged — the premium chocolate still cost exactly 14 cents more — so a purely rational shopper should not have switched. (④) The word “free,” it seems, does more than lower a cost to zero; it removes the possibility of loss altogether, and people value that sense of safety far beyond its monetary worth. (⑤) This is why companies so often prefer giving something away to merely discounting it.

> It now appears that each time a memory is retrieved, it becomes briefly unstable again, open to modification before being stored anew.

For much of the twentieth century, neuroscientists described memory formation as a one-way process. (①) A new experience was thought to be held for a while in a fragile state, then gradually "consolidated" into a stable trace that, once fixed, stayed fixed. (②) On this view, a well-established memory was like a document in an archive: it might fade or become hard to find, but its contents would not be rewritten. (③) Research over the past few decades has complicated this picture considerably. (④) This process, known as reconsolidation, means that remembering is not simply reading from storage but partly rebuilding what is stored. (⑤) It may help explain why vividly recalled memories, retold many times, can drift far from the original events while feeling no less certain.

[기본] 7 글의 흐름으로 보아, 주어진 문장이 들어가기에 가장 적절한 곳을 고르시오.

> Instead, the decision emerges from a simple rule followed by individual scouts, none of whom compares the options directly.

When a colony of rock ants loses its nest, it must choose a new home from several possible sites, and it usually picks the best one available. (①) What is remarkable is that no single ant surveys all the candidates and weighs them against one another. (②) A scout that finds a site waits before recruiting others, and the length of that wait depends on the site's quality — a short delay for a dry, dark cavity, a long one for a drafty one. (③) Because recruitment to better sites starts sooner, those sites accumulate ants more quickly. (④) Once the number of ants at a site passes a certain threshold, the scouts switch from slowly leading individual nestmates to rapidly carrying them, and the move is effectively settled. (⑤) The colony, in other words, behaves as if it had compared the options, though no member ever did.

> Without that comparison, a trait shared by winners tells us nothing about whether it helped them win.

Business books often follow a familiar recipe: select a group of highly successful companies, identify what they have in common, and present those shared traits as the secret of success. (①) The method feels rigorous, since the patterns it reveals are real; the successful firms genuinely did take bold risks, hire aggressively, or bet heavily on a single vision. (②) The trouble lies in whom the method never examines. (③) Many companies that failed — often quietly, leaving behind no case studies — may have taken exactly the same bold risks and made exactly the same bets. (④) To know whether boldness causes success, then, one must look not only at the firms that thrived but also at the comparable firms that tried the same strategy and disappeared. (⑤) Boldness may turn out to be less a recipe for success than a recipe for extreme outcomes, good and bad alike.
