When people expect to have future access to information, they are less likely to remember the information itself and more likely to remember where it can be found. This tendency, often labeled cognitive offloading, is not a symptom of laziness but a strategy ①that has served our species for millennia: long before search engines existed, individuals relied on spouses, elders, and written records to hold knowledge they did not need to carry ②themselves. What has changed is not the strategy but its scale. A device that answers almost any query within seconds ③encourages us to offload not merely facts but judgments, such as which route to take or whose opinion to trust. The danger lies less in forgetting than in never forming the internal structures ④which new information can be attached. An expert's knowledge is valuable precisely because it is organized, and such organization ⑤cannot be downloaded; it must be built through effortful retrieval.

Cities are often several degrees warmer than the surrounding countryside, a phenomenon (A) [known / knowing] as the urban heat island. Asphalt and concrete absorb solar radiation during the day and release it slowly after dark, so neighborhoods with little vegetation rarely get the relief that cooler evenings (B) [provide / providing] elsewhere. Planting trees seems an obvious remedy, yet its benefits are unevenly distributed. Wealthier districts, (C) [which / where] residents have the time and political connections to lobby city councils, tend to receive new plantings first, while poorer districts, which arguably need shade the most, wait for years. A policy meant to cool a city can thus end up widening the very inequalities it was supposed to ease.

	(A)	(B)	(C)
①	known	provide	which
②	known	provide	where
③	known	providing	where
④	knowing	provide	which
⑤	knowing	providing	where

When a measure becomes a target, it tends to lose its value as a measure. Consider a hospital evaluated by how quickly patients are seen after they arrive. At first, the waiting-time figure is a reasonable ①indicator of efficiency, since nobody has a reason to manipulate it. Once managers are rewarded for reducing it, however, they discover shortcuts: a nurse may greet patients briefly to stop the clock, even though actual treatment is still ②delayed. The number improves while the experience it was meant to capture stays the same or even ③deteriorates. The problem is not that people are dishonest; it is that any single number is ④sufficient as a description of a complex activity, and effort naturally flows toward whatever happens to be counted. The ⑤remedy, therefore, is not to abandon measurement but to rotate and combine indicators so that no single figure becomes worth gaming.

Introducing a predator to control an invasive pest can look like an elegant, chemical-free solution, but history counsels (A) [caution / confidence] . When cane toads were brought to Australia in 1935 to eat beetles that were damaging sugar cane, the toads proved largely (B) [indifferent / devoted] to their intended prey: the beetles spent much of their lives high on the cane stalks, out of reach, so the toads fed instead on whatever native animals they could find on the ground. With few natural enemies and a poison that killed many of the animals that tried to eat them, the toads spread across a vast area of the continent. Biologists learned a hard lesson from such failures. Today, a candidate control agent must demonstrate a (C) [specialized / generalized] diet before release, because a predator that feeds only on its target is far less likely to become a new pest once that target disappears.

	(A)	(B)	(C)
①	caution	indifferent	specialized
②	caution	indifferent	generalized
③	caution	devoted	specialized
④	confidence	devoted	generalized
⑤	confidence	indifferent	specialized

Placebos work not because sugar pills contain hidden medicine but because expectation itself (a)alters how the brain processes signals from the body. In one study, patients who were told openly that they were receiving a placebo still reported less pain than those (b)received no treatment at all. Researchers suspect that the ritual of treatment—the white coat, the prescription, the instruction to take a pill twice a day—(c)triggers learned associations between care and relief. This finding challenges the assumption that deception is essential, and it raises the possibility that doctors might harness placebo effects (d)honest. Still, the effect has clear limits: a placebo can ease the perception of symptoms, but it rarely shrinks a tumor or (e)lowering a fever.

Engineers often add redundancy to critical systems: a second pump, a backup power line, an extra sensor. Intuitively, each addition should make failure less ①likely. Yet redundancy can ②undermine safety in subtle ways. Additional components increase a system's complexity, creating new interactions that designers did not ③anticipate. Moreover, operators who know a backup exists may become less ④vigilant, assuming that any single failure will simply be absorbed. Most troubling, redundant parts often share hidden dependencies—the same supplier, the same maintenance crew, the same software—so a single cause can disable them ⑤separately, defeating the very independence on which redundancy depends.

Had researchers measured memory only immediately after learning, they (A) [would have missed / had missed] one of the most striking findings in cognitive science: memories often grow stronger while we sleep. During deep, slow-wave sleep, the brain replays the day's experiences, (B) [transferring / transferred] them from the hippocampus to the cortex, where they can be stored for the long term. Not only (C) [does this process stabilize / this process stabilizes] fragile memories, but it also appears to extract general patterns from specific episodes, which may explain why people who sleep on a difficult problem sometimes wake up with a solution. Sleep, in other words, is not a pause in learning but one of its essential stages.

	(A)	(B)	(C)
①	would have missed	transferred	this process stabilizes
②	had missed	transferring	does this process stabilize
③	would have missed	transferred	does this process stabilize
④	had missed	transferred	this process stabilizes
⑤	would have missed	transferring	does this process stabilize

Paying people to do something they already enjoy can, paradoxically, make them do less of it. In a classic line of experiments, children who ①had been drawing happily on their own were promised a reward for their pictures; once the rewards stopped, they spent less free time drawing than children who ②had never rewarded. Psychologists explain this pattern by pointing out that a payment changes ③how an activity is understood: what was once done for its own sake begins to look like work done for someone else. The effect is far from universal, however. Rewards that arrive unexpectedly, or that are framed as recognition rather than as a means of control, rarely ④reduce interest, and some tasks are so dull that there is no intrinsic motivation ⑤to be destroyed in the first place.
